

Constructed Climates

A Primer on Urban Environments

Will Wilson

The University of Chicago Press

Chicago and London

Contents

Preface	v
1 Cities and Nature	2
Human population increased six-fold over the last century.	4
Water, warmth, and light makes plants grow.	6
High evapotranspiration promotes biodiversity.	8
Humans exceed the natural population density for their body size.	10
The last century brought increased agricultural efficiency.	12
Fossil-fuel based nitrogen production increased crop yields.	14
Urban land-use grew as small farms disappeared.	16
Cities change ecological communities.	18
Agricultural and urban land-use reduce stream water quality.	20
Impervious surfaces in urbanized watersheds hurt organisms.	22
Durham rainfall exceeds regulated basin sizes.	24
Reservoirs reduce sediments while providing water.	26
2 Shading and Cooling in City Climates	28
Low vegetation and high temperature in Durham.	30
Low vegetation and high temperature in Indianapolis.	32
Low temperature correlates with high vegetation.	34
Urban heat islands spawn thunderstorms.	36
Cities change rainfall patterns.	38
Lightning strikes reflect urban weather changes.	40
Cities grow warmer.	42
Closed-in urban areas have higher heat islands.	44
The urban heat island may be weak while Earth warms.	46
Equal heat in lots of air, sprinkling of water, and asphalt road.	48
Whiter surfaces are cooler.	50

Parking lot trees could provide shade.	52
Big trees could provide lots of shade.	54
Bigger and younger trees transpire more water.	56
Trees near asphalt stop transpiring early in the day.	58
Evapotranspiration from watersheds and lawns.	60
New developments can plan for shade.	62
Paving and grass can be combined.	64
3 Energy Use and Carbon Budgets	66
U.S. energy sources have changed.	68
States vary in their gasoline and electricity use.	70
Per capita energy use depends on a state's population density.	72
Economic productivity correlates with energy use.	74
Photosynthesis links carbon, water, nitrogen, and sunlight.	76
Atmospheric CO ₂ increased with human emissions.	78
Global warming changes nature.	80
Species have different features in urban and rural environments.	82
Soils contribute to carbon budgets.	84
Vegetation stores and sequesters carbon.	86
Urban pruning can be very intensive.	88
Carbon costs of landscaping machines is high.	90
Durham citizens export their carbon sequestration.	92
Trees and white paint reduce energy consumption.	94
Trees help small houses keep cool and break-even for heating.	96
Wood has low energy content.	98
Durham citizens use more energy than local forests can provide.	100
4 Emissions and Urban Air	102
Human sources of volatile organic compounds (VOCs).	104
Fossil fuel use produces many pollutants.	106
Trees also produce volatile organic compounds.	108
VOCs produced by trees vary across the contiguous United States.	110
Trees produce more VOCs in bright light and high heat.	112
VOC sources vary in place and time.	114
VOCs, reactive nitrogen, and sunlight lead to ground-level ozone.	116
Large pollution inputs lead to high downwind ozone levels later.	118
Ozone production has a complicated emissions dependence.	120
Ozone: Wednesday through Saturday, March through September.	122

Ozone in rural areas increase with temperature and nitrogen. . . .	124
When it's hot, urban ozone levels exceed regulatory allowances. . .	126
High ozone levels harm vegetation.	128
Air pollution varies greatly in space and time.	130
5 Social Aspects of Urban Nature	132
What's the value of Chickpea?	134
S.A. Forbes 1880: The value of birds.	136
Trees make satisfying neighborhoods.	138
People like neat trees, not messy forests.	140
Park features, scenic beauty, and perceived security.	142
Underbrush was bad as far back as 1285.	144
About ten out of ten people prefer malls.	146
Varying tree cover in Chicago public housing.	148
Reduced vegetation correlates with higher crime.	150
Girls' self-discipline develops better with nature.	152
Nature promotes emotional and physical health.	154
Trees promote bird and plant species richness.	156
6 Human Health and Urban Inequities	158
Heat waves lead to deaths a few days later.	160
Particulate matter is bad for older people.	162
High ozone and SO ₂ levels predict high asthma hospitalizations. .	164
Asthma incidence and pollution aren't tightly correlated through time.	166
Though cities differ, heat kills people in July and August.	168
Air conditioning reduces heat related mortality.	170
Many people die in winter, accounting for age, race, and gender. .	172
Lower income, fewer trees, and higher temperatures go together in Durham.	174
Wealth, homeownership, and trees connect in Milwaukee, WI. . .	176
Wealth, education, and vegetation correlate in Baltimore, MD. . .	178
Parks, trees, and plants come with wealth.	180
Minority populations have worse air, income, and asthma.	182
Healthier neighborhoods are usually wealthier neighborhoods. . .	184
Income helps education and increases life expectancy.	186
7 Summary and Implications	188

A Graphical Intuitions	195
Three equivalent data representations.	196
Graphing visual correlations.	198
Importance versus significance.	200
Plotting transformed data.	202
Quantities covary.	204
Sample sizes and measures of variation.	206
Endnotes	208
References	242
Index	266
